GENERAL FRAMEWORK

what we learn from the
baseline

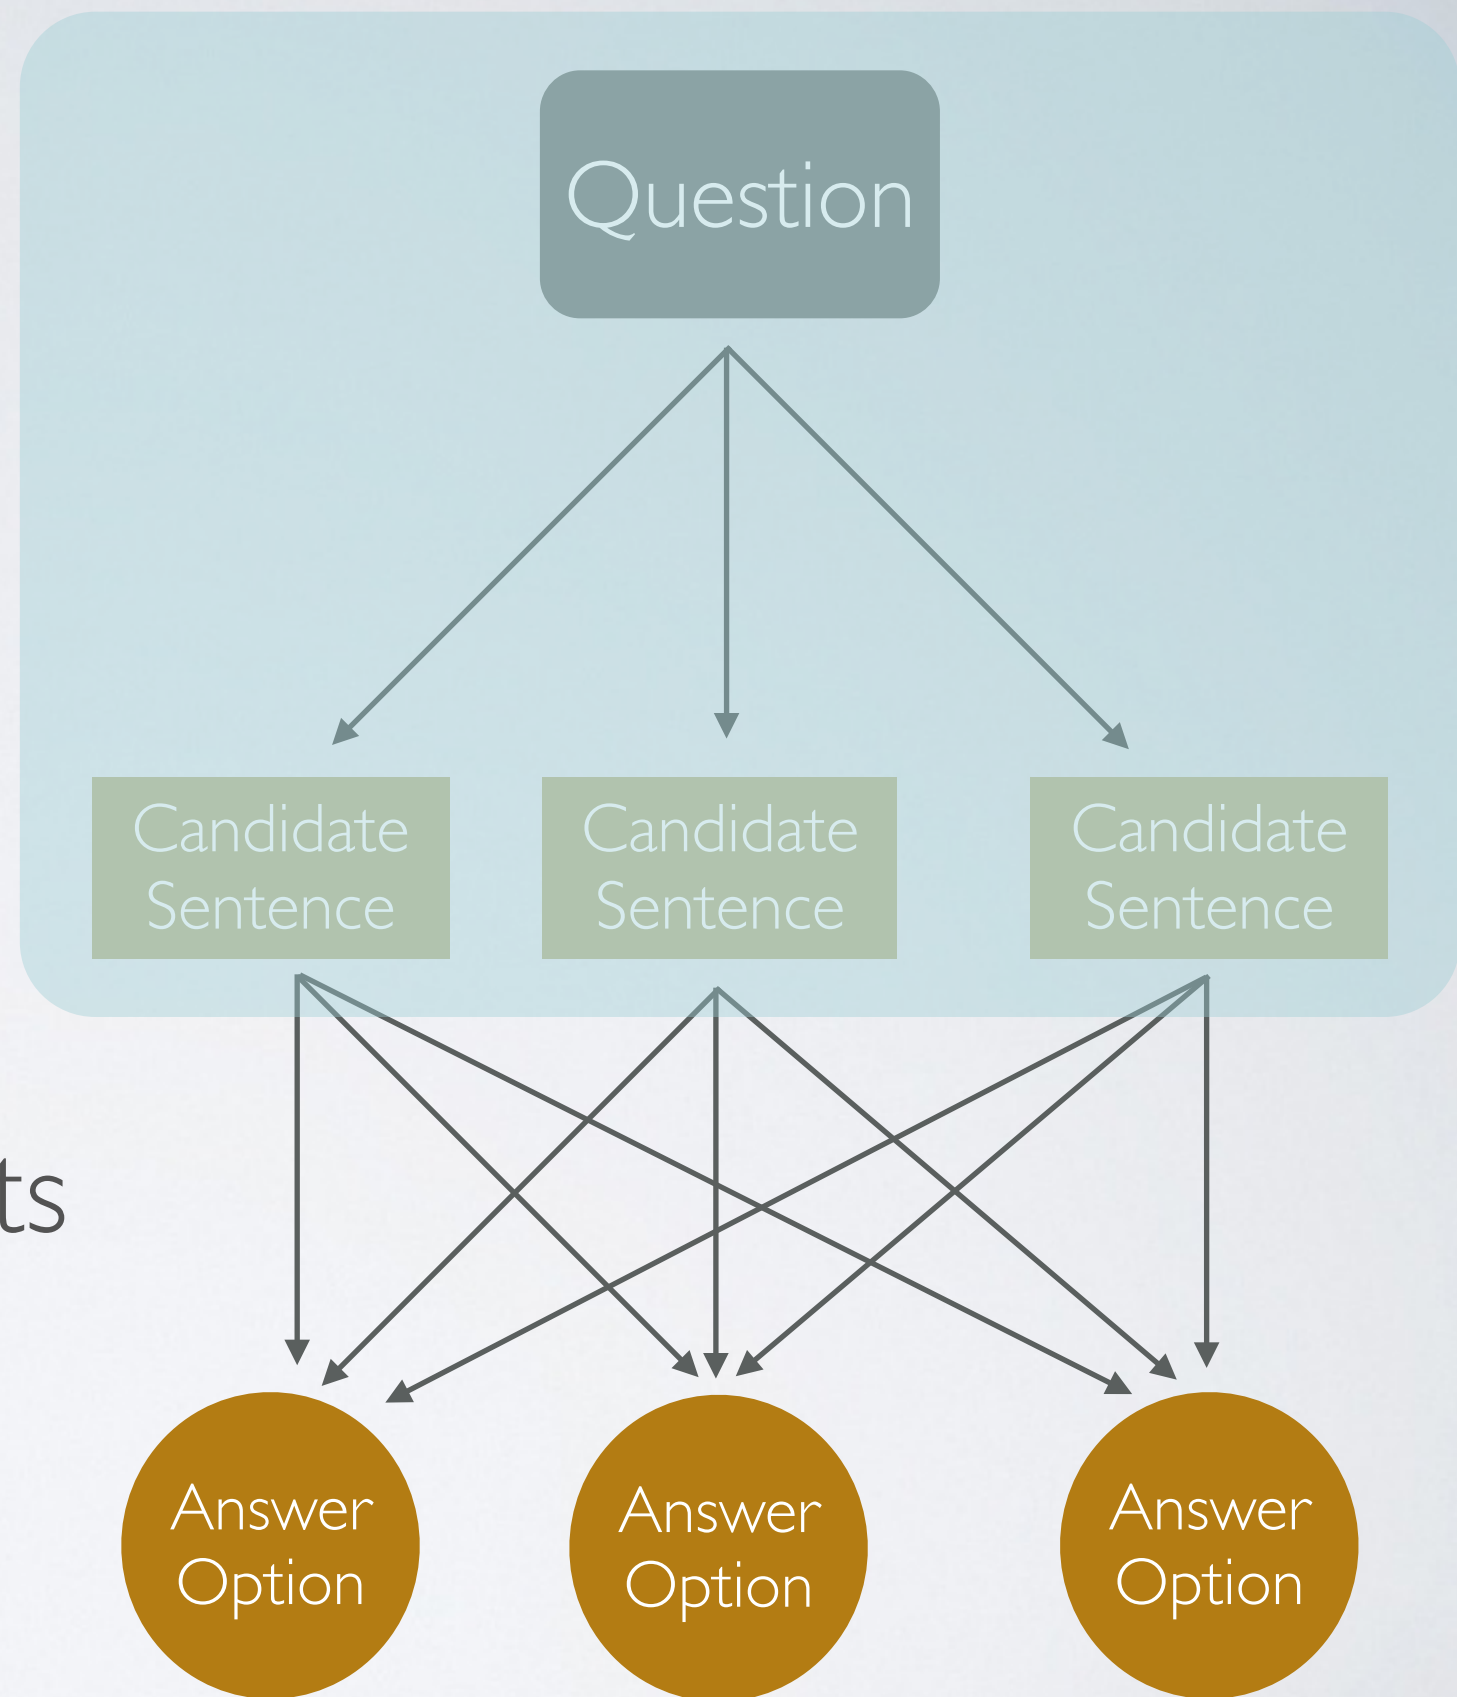

CANDIDATE SENTENCE SELECTION

Baseline Method:

Solr with NP, NER, etc.

Drawbacks:

- * a black-box tool
- * hard to tune weights for different features
- * hard to use non-BoW features

Proposed Method:

Language Model Framework
with supervised weights

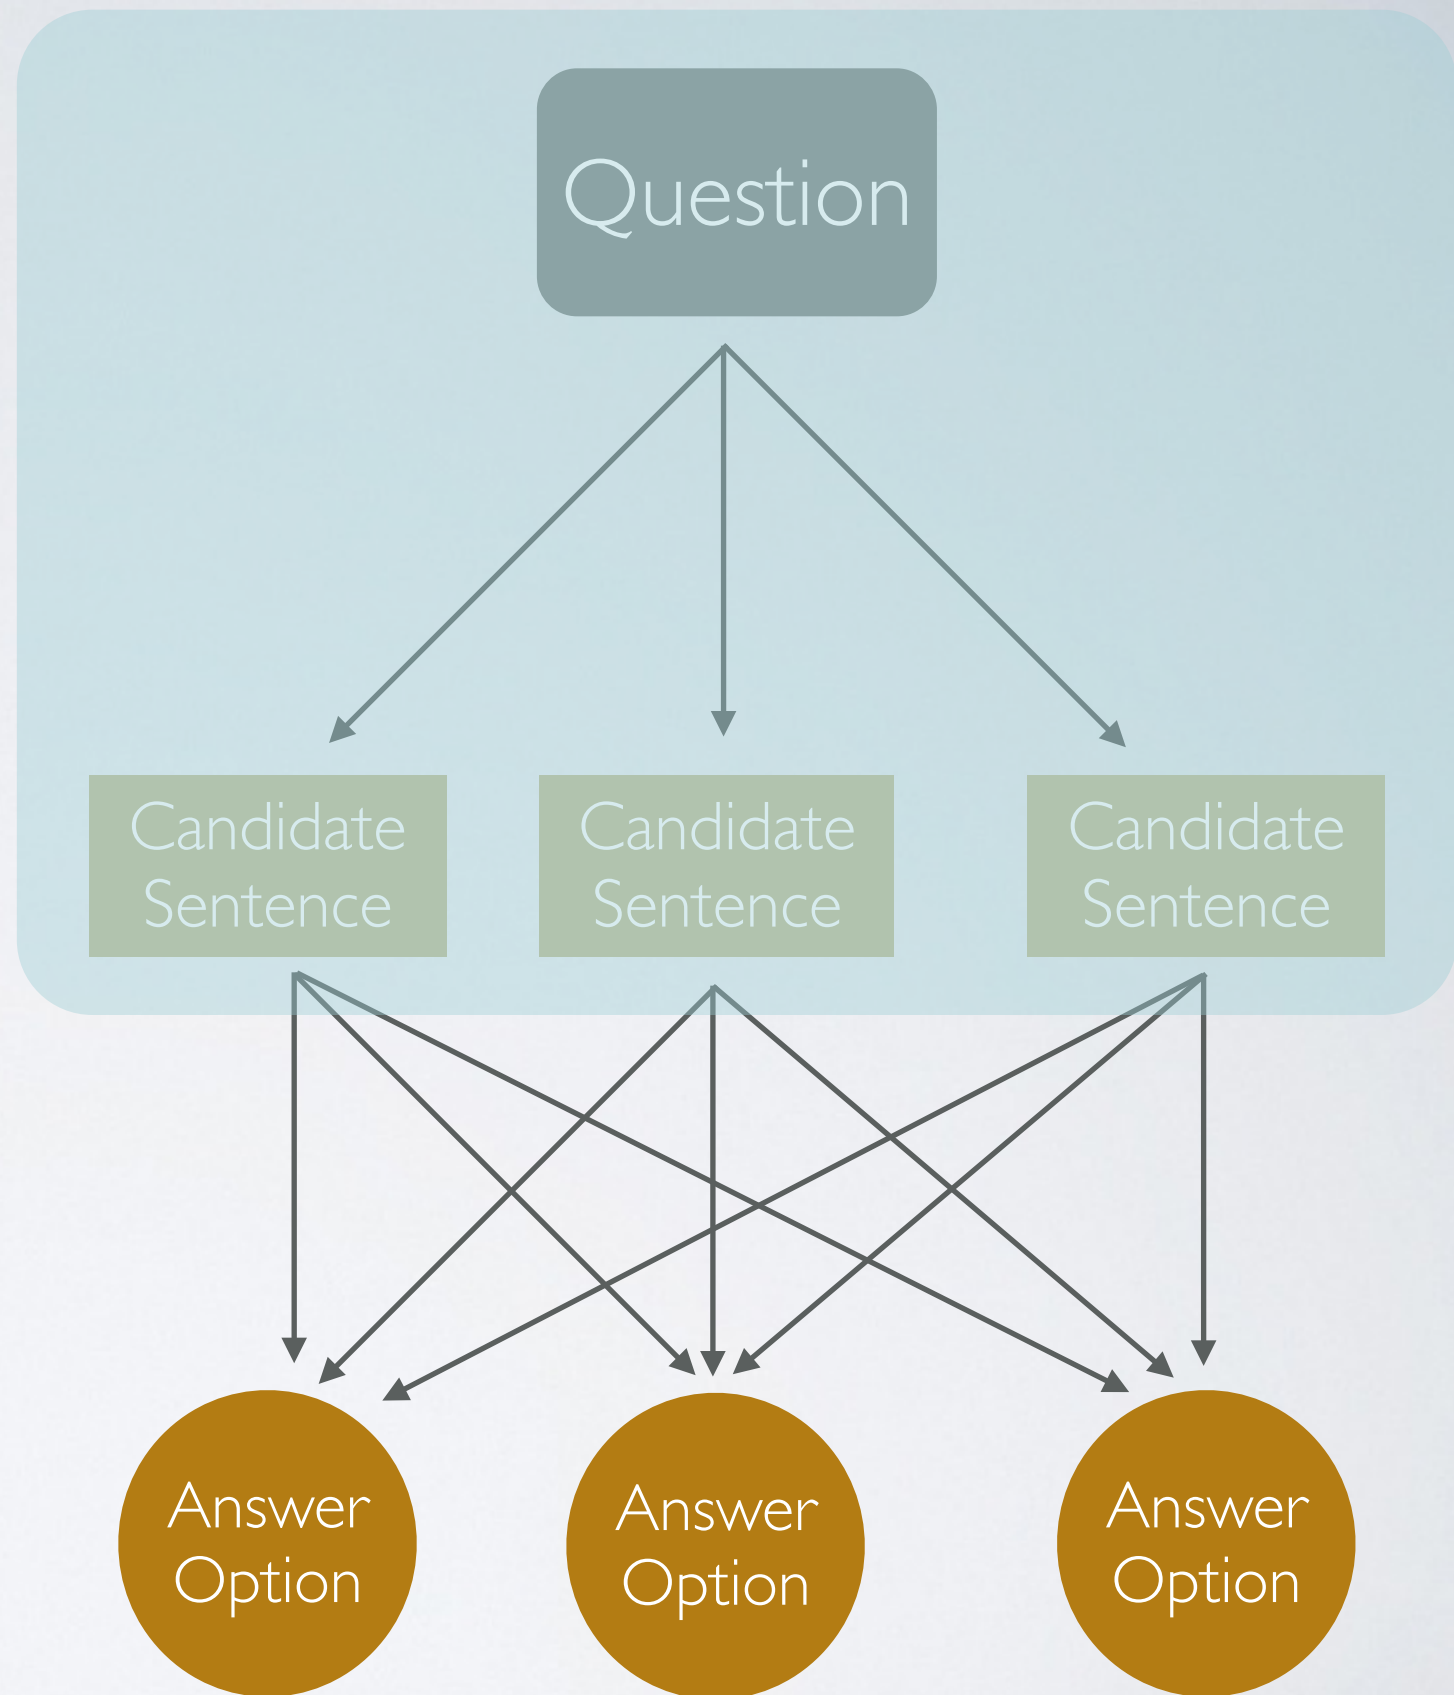

$$f(q, s_i) = p(q|s_i) = \sum_k \alpha_k p(v_k(q)|v_k(s_i))$$

Features:

Lexical features: unigram,
bigram,
NER, NP, dependency parsing

Syntactic features: pos tags,
parsing tree

Semantic features: adjacency in
WordNet, freebase, other BIO
background database

Proposed by Chenyan

ANSWER SCORE BASED ON CANDIDATE SENTENCES

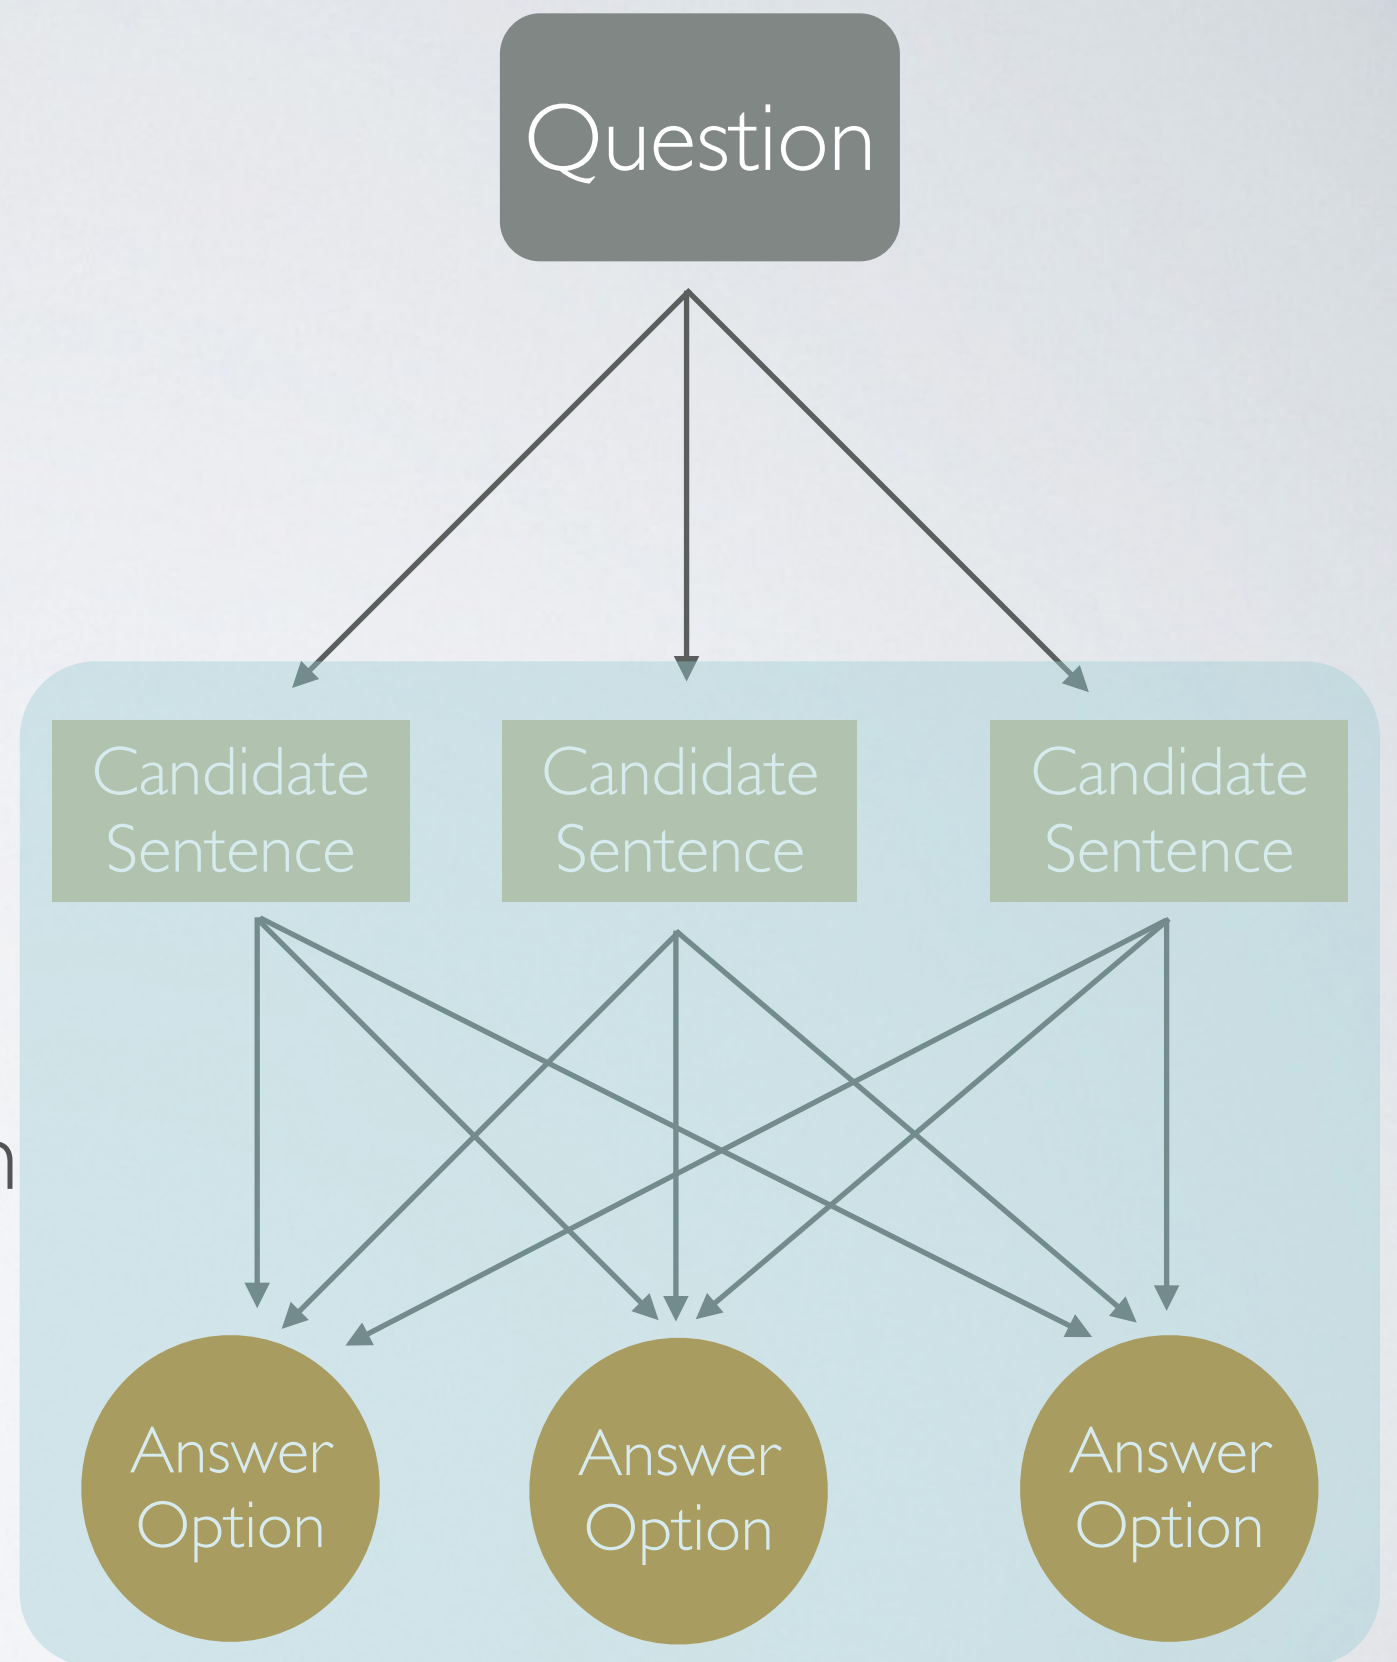

Baseline Method:

Joint voting with Similarity Score and PIM score in background documents

Drawbacks:

* Joint voting has a bias on answers with frequent terms

* Relevance with Question is ignored here

ANSWER SCORE BASED ON CANDIDATE SENTENCES

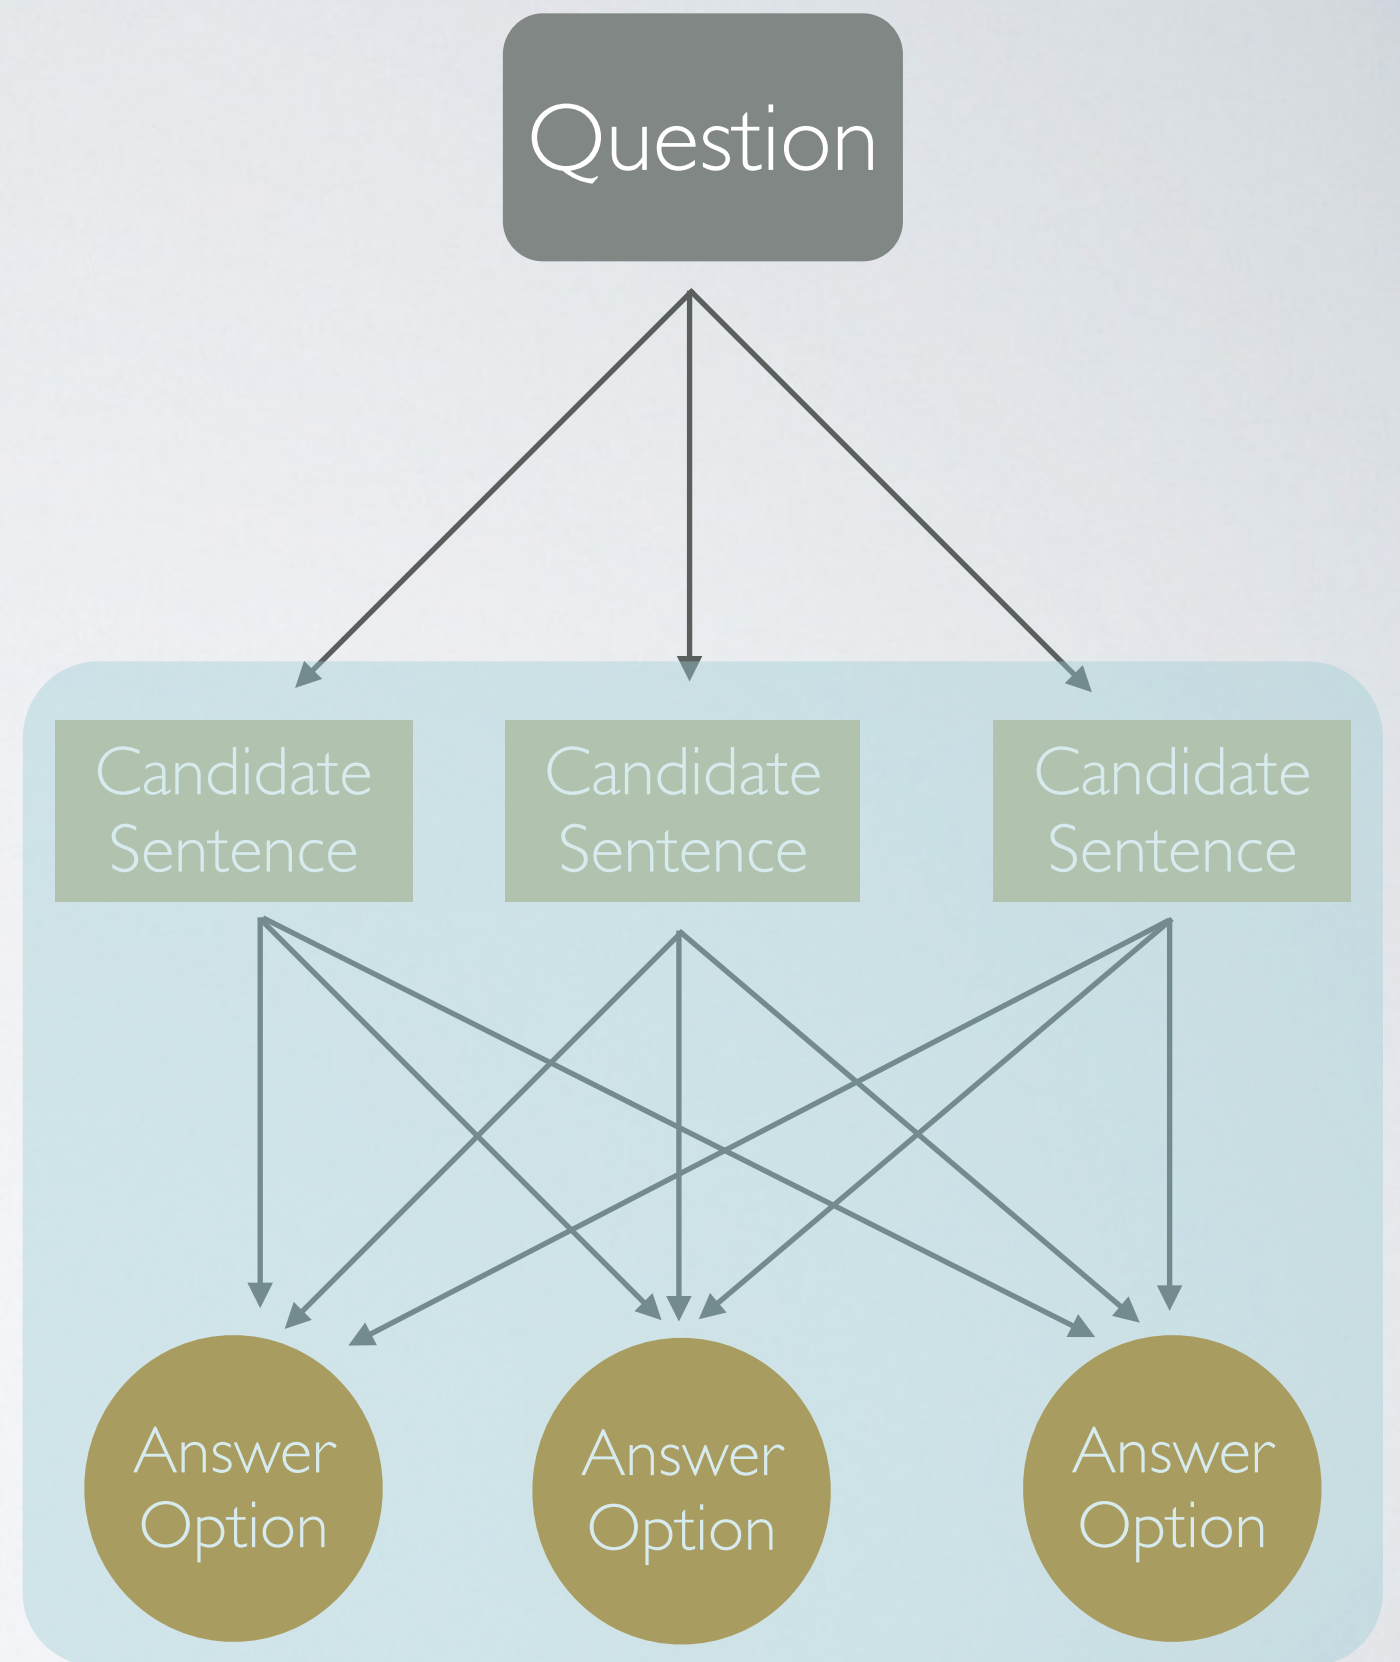

Proposed Method:

Lexical Features:

- * Cosine Similarity
- * Jaccard Similarity
- * Dice Similarity

Semantic Features:

- * Semantic Role of the “what/how/why” word compared with the answer word in the candidate sentence

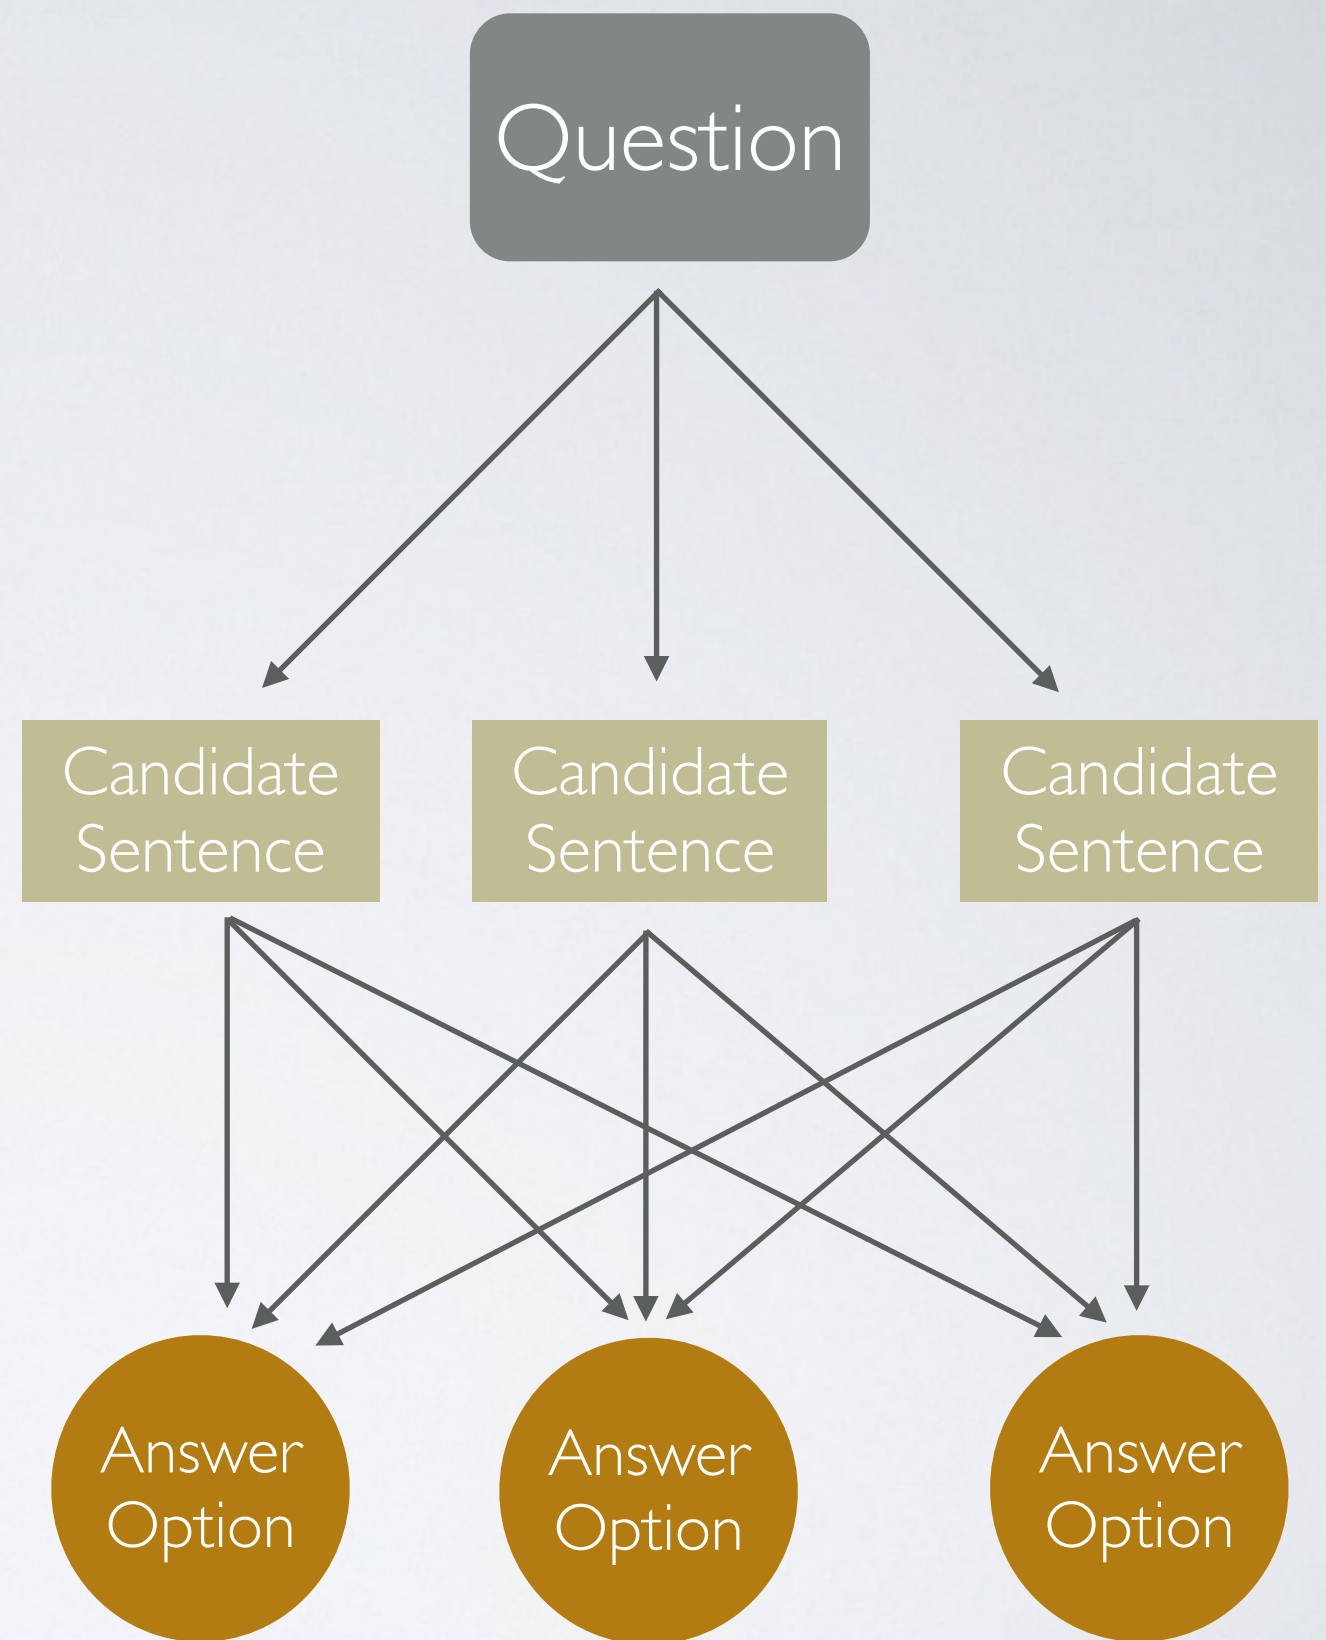

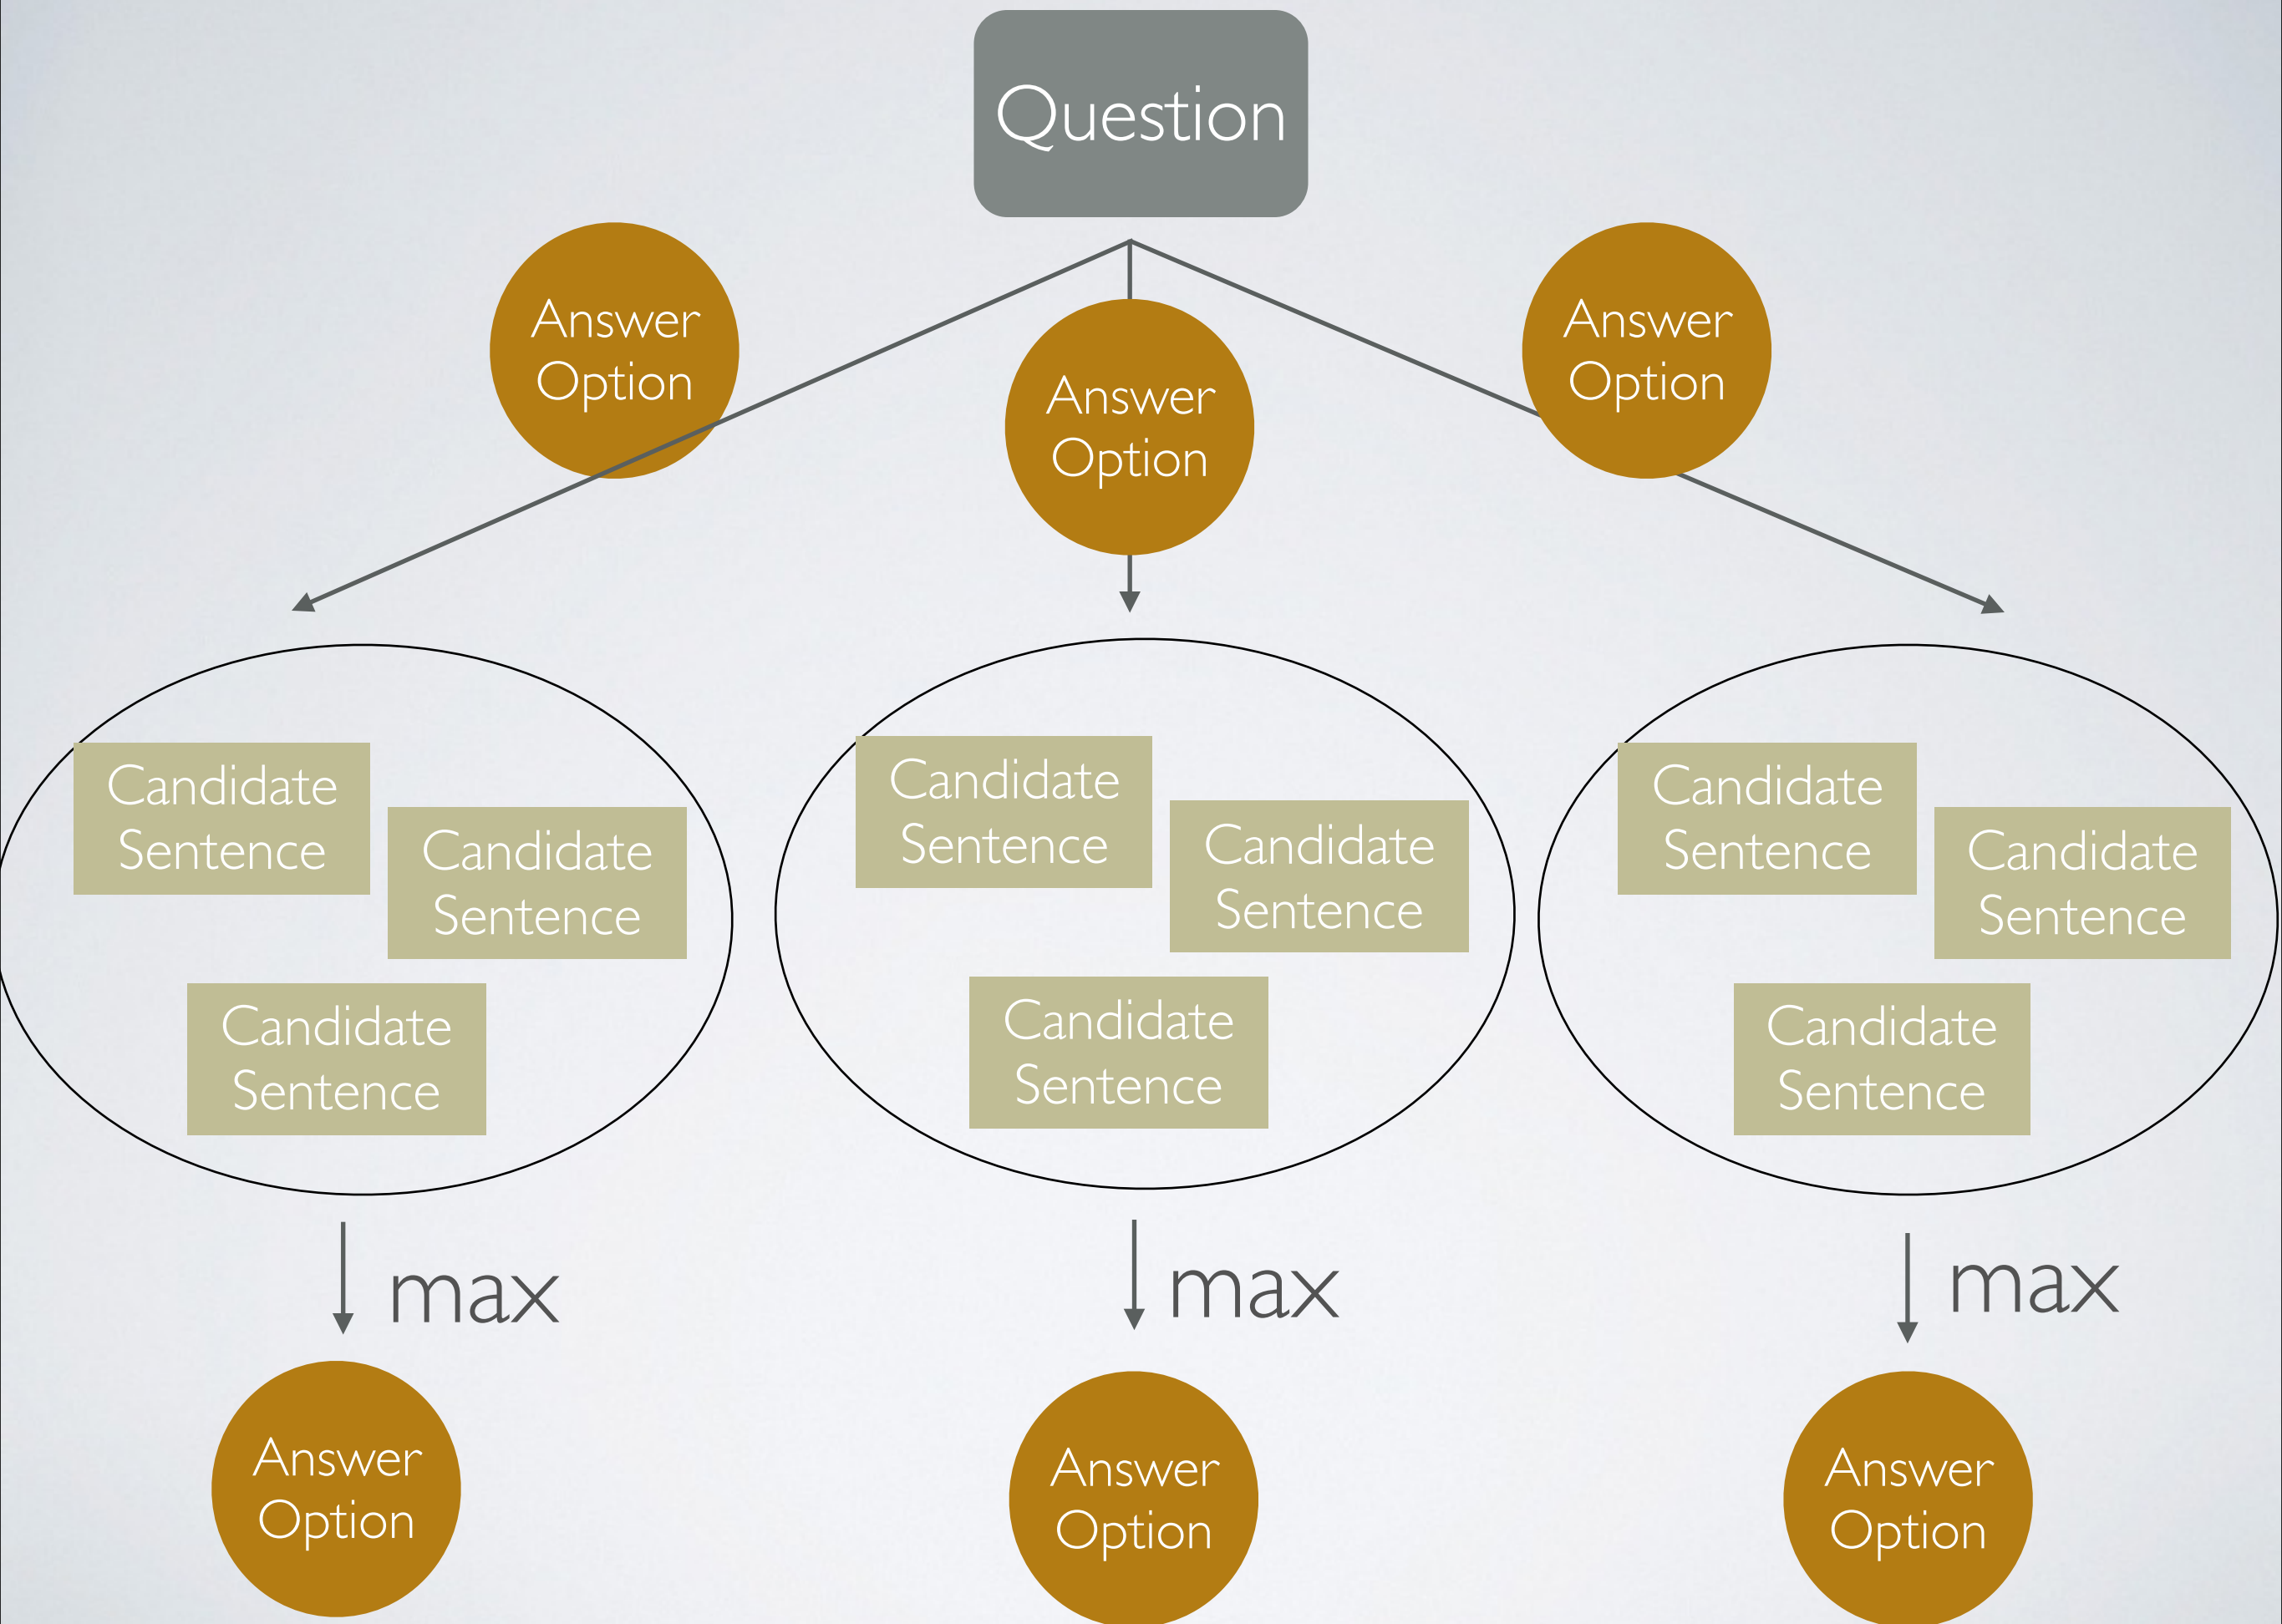

Proposed by Vinay and Bo

PROBLEMS WITH THE FRAMEWORK

* Good candidate sentences **cannot** be selected from only the question

* The relation between the question and answer is never measured directly.

Question

Key Idea

* Use answer options as well to rank candidate sentences, so that each answer has its own candidate sentence list

* Use the best score instead of a joint vote

* Use the ranking score inside the score of answer option

Answer Option

Answer Option

Answer Option

CURRENT STATUS

- Changed the type system to support our design on the framework
- Still using Solr query to find candidate sentence, but add answer to the query
- Performance on 2012 test set:
 - Baseline:
 - 20% (3/10, 1/10, 1/10, 3/10)
 - Our current methods:
 - 27.5% (3/10, 4/10, 2/10, 2/10)
